

## Answer 6.7

Identify the unknown from its 70 eV EI mass spectrum.

First, crawl across the mass spectrum to identify typical isotopic patterns, obvious mass differences, i.e., neutral losses, and/or well-known fragment ions or fragment ion series:

The monoisotopic molecular ion peak is at  $m/z$  250 and exhibits a  $\text{Br}_3$  isotopic pattern (250, 252, 254, 256). Even mass indicates 0, 2, 4, ... nitrogen atoms.  $^{13}\text{C}$  peaks are very small, i.e., there are very few carbon atoms.

$m/z$ 171, 173, 175	$\text{Br}_2$ pattern, $[\text{M}-79] \rightarrow [\text{M}-\text{Br}]^+$
$m/z$ 158, 160, 162	$\text{Br}_2$ pattern $\rightarrow \text{Br}_2^{++}$
$m/z$ 92, 94	$\text{Br}$ pattern, $[\text{M}-158] \rightarrow [\text{M}-\text{Br}_2]^{++}$
$m/z$ 91, 93	$\text{Br}$ pattern, $[\text{M}-159] \rightarrow [\text{M}-\text{Br}-\text{HBr}]^+$
$m/z$ 80, 82	$\text{Br}$ pattern $\rightarrow \text{HBr}^{++}$
$m/z$ 79, 81	$\text{Br}$ pattern $\rightarrow \text{Br}^+$

As we have 3 bromines, the remaining mass of the unknown is  $250 \text{ u} - 3 \times 79 \text{ u} = 13 \text{ u}$  which should correspond to  $\text{CH}$ .

Thus, the molecular formula most probably is  $\text{CHBr}_3$ ;  $r+d = 1 - 0.5 \times (1 + 3) + 1 = 0$

There is only one reasonable isomer of bromoform.

Fragmentation scheme (analogous to  $\text{CH}_4$  and  $\text{CH}_3\text{I}$ ):
